Quasi-Sectorial Contractions

Valentin A. Zagrebnov

Université de la Méditerranée (Aix-Marseille II) and Centre de Physique Théorique - UMR 6207, Luminy-Case 907, 13288 Marseille Cedex 9, France

Abstract

We revise the notion of the quasi-sectorial contractions. Our main theorem establishes a relation between semigroups of quasi-sectorial contractions and a class of \(m\)-sectorial generators. We discuss a relevance of this kind of contractions to the theory of operator-norm approximations of strongly continuous semigroups.

**Key words:** Operator numerical range; \(m\)-sectorial generators; contraction semigroups; quasi-sectorial contractions; holomorphic semigroups; semigroup operator-norm approximations.

**PACS:** 47A55, 47D03, 81Q10

1 Sectorial Operators

Let \(\mathcal{H}\) be a separable Hilbert space and let \(T\) be a densely defined linear operator with domain \(\text{dom}(T) \subset \mathcal{H}\).

**Definition 1.1** The set of complex numbers:

\[
\mathfrak{N}(T) := \{(u, Tu) \in \mathbb{C} : u \in \text{dom}(T), \|u\| = 1\},
\]

is called the numerical range of the operator \(T\).

**Remark 1.1** (a) It is known that the set \(\mathfrak{N}(T)\) is convex (the Toeplitz-Hausdorff theorem), and in general is neither open nor closed, even for a closed operator \(T\).

(b) Let \(\Delta := \mathbb{C} \setminus \overline{\mathfrak{N}(T)}\) be complement of the numerical range closure in the complex plane. Then \(\Delta\) is a connected open set except the special case, when \(\overline{\mathfrak{N}(T)}\) is a strip bounded by two parallel straight lines.

Preprint submitted to Elsevier Science
Below we use some important properties of this set, see e.g. [7, Ch.V], or [11, Ch.1.6]. Recall that \( \dim(\text{ran}(T))^\perp =: \text{def}(T) \) is called a deficiency (or defect) of a closed operator \( T \) in \( \mathcal{H} \).

**Proposition 1.1** (i) Let \( T \) be a closed operator in \( \mathcal{H} \). Then for any complex number \( z \notin \mathcal{R}(T) \), the operator \( (T - zI) \) is injective. Moreover, it has a closed range \( \text{ran}(T - zI) \) and a constant deficiency \( \text{def}(T - zI) \) in each of connected component of \( \mathbb{C} \setminus \mathcal{R}(T) \).

(ii) If \( \text{def}(T - zI) = 0 \) for \( z \notin \mathcal{R}(T) \), then \( \Delta \) is a subset of the resolvent set \( \rho(T) \) of the operator \( T \) and

\[
\| (T - zI)^{-1} \| \leq \frac{1}{\text{dist}(z, \mathcal{R}(T))}.
\]

(iii) If \( \text{dom}(T) \) is dense and \( \mathcal{R}(T) \neq \mathbb{C} \), then \( T \) is closable, hence the adjoint operator \( T^* \) is also densely defined.

**Corollary 1.1** For a bounded operator \( T \in \mathcal{L}(\mathcal{H}) \) the spectrum \( \sigma(T) \) is a subset of \( \mathcal{R}(T) \).

For unbounded operator \( T \) the relation between spectrum and numerical range is more complicated. For example, it may very well happen that \( \sigma(T) \) is not contained in \( \mathcal{R}(T) \), but for a closed operator \( T \) the essential spectrum \( \sigma_{\text{ess}}(T) \) is always a subset of \( \mathcal{R}(T) \). The condition \( \text{def}(T - zI) = 0 \), \( z \notin \mathcal{R}(T) \) in Proposition 1.1 (ii) serves to ensure that for those unbounded operators one gets

\[
\sigma(T) \subset \mathcal{R}(T),
\]

i.e., the same conclusion as in Corollary 1.1 for bounded operators.

**Definition 1.2** Operator \( T \) is called sectorial with semi-angle \( \alpha \in (0, \pi/2) \) and a vertex at \( z = 0 \) if

\[
\mathcal{R}(T) \subseteq S_\alpha := \{ z \in \mathbb{C} : |\arg z| \leq \alpha \}.
\]

If, in addition, \( T \) is closed and there is \( z \in \mathbb{C} \setminus S_\alpha \) such that it belongs to the resolvent set \( \rho(T) \), then operator \( T \) is called \( m \)-sectorial.

**Remark 1.2** Let \( T \) be \( m \)-sectorial with the semi-angle \( \alpha \in (0, \pi/2) \) and the vertex at \( z = 0 \). Then it is obvious that the operators \( aT \) and \( T_b := T + b \) belong to the same sector \( S_\alpha \) for any non-negative parameters \( a, b \geq 0 \). In fact \( \mathcal{R}(T_b) \subseteq S_\alpha + b \), i.e. the operator \( T_b \) has the vertex at \( z = b \).

Some of important properties of the \( m \)-sectorial operators are summarized by the following
Proposition 1.2 If \( T \) is \( m \)-sectorial in \( \mathfrak{H} \), then the semigroup \( \{U(\zeta) : e^{-\zeta T}\} \) generated by the operator \( T \):

(i) is holomorphic in the open sector \( \{\zeta \in S_{\pi/2-\alpha}\} \);

(ii) is a contraction, i.e. \( \mathfrak{R}(U(\zeta)) \) is a subset of the unit disc \( \mathfrak{D}_{r=1} := \{z \in \mathbb{C} : |z| \leq 1\} \) for \( \{\zeta \in S_{\pi/2-\alpha}\} \).

2 Quasi-Sectorial Contractions and Main Theorem

The notion of the quasi-sectorial contractions was introduced in [4] to study the operator-norm approximations of semigroups. In paper [3] this class of contractions appeared in analysis of the operator-norm error bound estimate of the exponential Trotter product formula for the case of accretive perturbations. Further applications of these contractions which, in particular, improve the rate of convergence estimate of [4] for the Euler formula, one can find in [9], [2] and [1].

Definition 2.1 For \( \alpha \in [0, \pi/2) \) we define in the complex plane \( \mathbb{C} \) a closed domain:

\[
D_\alpha := \{z \in \mathbb{C} : |z| \leq \sin \alpha\} \cup \{z \in \mathbb{C} : |\arg(1-z)| \leq \alpha \text{ and } |z-1| \leq \cos \alpha\}.
\]

This is a convex subset of the unit disc \( \mathfrak{D}_{r=1} \), with "angle" (in contrast to tangent) touching of its boundary \( \partial \mathfrak{D}_{r=1} \) at only one point \( z = 1 \), see Figure 1. It is evident that \( D_\alpha \subset D_{\beta > \alpha} \).

Definition 2.2 (Quasi-Sectorial Contractions [4]) A contraction \( C \) on the Hilbert space \( \mathfrak{H} \) is called quasi-sectorial with semi-angle \( \alpha \in [0, \pi/2) \) with respect to the vertex at \( z = 1 \), if \( \mathfrak{R}(C) \subset D_\alpha \).

Notice that if operator \( C \) is a quasi-sectorial contraction, then \( I - C \) is an \( m \)-sectorial operator with vertex \( z = 0 \) and semi-angle \( \alpha \). The limits \( \alpha = 0 \) and \( \alpha = \pi/2 \) correspond, respectively, to non-negative (i.e. self-adjoint) and to general contraction.

The resolvent of an \( m \)-sectorial operator \( A \), with semi-angle \( \alpha \in (0, \pi/4] \) and vertex at \( z = 0 \), gives the first non-trivial (and for us a key) example of a quasi-sectorial contraction.

Proposition 2.1 Let \( A \) be \( m \)-sectorial operator with semi-angle \( \alpha \in [0, \pi/4] \) and vertex at \( z = 0 \). Then \( \{F(t) := (I+tA)^{-1}\}_{t>0} \) is a family of quasi-sectorial contractions which numerical ranges \( \mathfrak{R}(F(t)) \subset D_\alpha \) for all \( t \geq 0 \).
Proof: First, by virtue of Proposition 1.1 (ii) we obtain the estimate:
\[
\|F(t)\| \leq \frac{1}{t \text{ dist}(1/t, -S_\alpha)} = 1 ,
\] (2.1)
which implies that operators \( \{F(t)\}_{t \geq 0} \) are contractions with numerical ranges \( \mathcal{R}(F(t)) \subseteq \mathcal{D}_{r=1} \).

Next, by Remark 1.2 for all \( u \in \mathcal{H} \) one gets
\[
(u, F(t)u) = (v_t, v_t) + t(Av_t, v_t) \in S_\alpha ,
\]
where \( v_t := F(t)u \). Especially, one finds that
\[
(I - F(t))u = t(v, Av) + t^2(Av, Av) \in S_\alpha ,
\]
and \( \mathcal{R}(I - F(t)) \subseteq S_\alpha \). Therefore, for all \( t \geq 0 \) we obtain:
\[
\mathcal{R}(F(t)) \subseteq (S_\alpha \cap (1 - S_\alpha)) \subseteq \mathcal{D}_{r=1} .
\] (2.2)

Moreover, since \( \alpha \leq \pi/4 \), by Definition 2.1 we get \( (S_\alpha \cap (1 - S_\alpha)) \subseteq D_\alpha \), i.e. for these values of \( \alpha \) the operators \( \{F(t)\}_{t \geq 0} \) are quasi-sectorial contractions with numerical ranges in \( D_\alpha \).\( \square \)

Now we are in position to prove the main Theorem establishing a relation between quasi-sectorial contraction semigroups and a certain class of \( m \)-sectorial generators.

**Theorem 2.1** Let \( A \) be an \( m \)-sectorial operator with semi-angle \( \alpha \in [0, \pi/4] \) and with vertex at \( z = 0 \). Then \( \{e^{-tA}\}_{t \geq 0} \) is a quasi-sectorial contraction semigroup with numerical ranges \( \mathcal{R}(e^{-tA}) \subseteq D_\alpha \) for all \( t \geq 0 \).

The proof of the theorem is based on a series of lemmata and on the numerical range mapping theorem by Kato [8] (see also an important comment about this theorem in [10]).

**Proposition 2.2** [8] Let \( f(z) \) be a rational function on the complex plane \( \mathbb{C} \), with \( f(\infty) = \infty \). Let for some compact and convex set \( E' \subset \mathbb{C} \) the inverse function \( f^{-1} : E' \mapsto E \supseteq K \), where \( K \) is a convex kernel of \( E \), i.e., a subset of \( E \) such that \( E \) is star-shaped relative to any \( z \in K \).

If \( C \) is an operator with numerical range \( \mathcal{R}(C) \subseteq K \), then \( \mathcal{R}(f(C)) \subseteq E' \).

Notice that for a convex set \( E \) the corresponding convex kernel \( K = E \).

**Lemma 2.1** Let \( f_n(z) = z^n \) be complex functions, for \( z \in \mathbb{C} \) and \( n \in \mathbb{N} \). Then the sets \( f_n(D_\alpha) \) are convex and domains \( f_n(D_\alpha) \subseteq D_\alpha \) for any \( n \in \mathbb{N} \), if \( \alpha \leq \pi/4 \).
Lemma 2.2 (Euler formula) Let $A$ be an $m$-sectorial operator. Then for $t \geq 0$ one gets the strong limit
\[ s - \lim_{n \to \infty} (F(t/n))^n = e^{-tA}. \] (2.3)

The next section is reserved for the proofs. They refine and modify some lines of reasonings of the paper [4]. This concerns, in particular, a corrected proofs of Proposition 2.1 and Theorem 2.1 (cf. Theorem 2.1 of [4]), as well as reformulations and proofs of Propositions 2.2 and Lemma 2.1.

3 Proofs

Proof (Lemma 2.1):
Let \( \{z : |z| \leq \sin \alpha \} \subset D_\alpha \), then one gets \(|z^n| \leq \sin \alpha\). Therefore, for the mappings \( f_n : z \mapsto z^n \) one obtains \( f_n(z) \in D_\alpha \) for any \( n \geq 1 \).

Thus, it rests to check the same property only for images \( f_n(G_\alpha), n \geq 1 \) of the sub-domain:
\[ G_\alpha := \{z : |\arg(z)| < (\pi/2 - \alpha) \} \cap \{z : |\arg(z + 1)| > (\pi - \alpha)\} \subset D_\alpha, \] (3.1)
see Definition 2.1 and Figure 1.

For \( 0 \leq t \leq \cos \alpha \), two segments of tangent straight intervals:
\[ \{\zeta_\pm(t) = 1 + t e^{i(\pi \pm \alpha)}\}_{0 \leq t \leq \cos \alpha} \subset \partial D_\alpha, \]
are correspondingly upper \( \zeta_+(t) \) and lower \( \zeta_-(t) = \overline{\zeta_+(t)} \) non-arc parts of the total boundary \( \partial D_\alpha \); they also coincide with a part of the boundary \( \partial G_\alpha \) connected to the vertex \( z = 1 \).

Now we proceed by induction. Let \( n = 1 \). Then one obviously obtain:
\[ f_{n=1}(D_\alpha) = D_\alpha. \] For \( n = 2 \) the boundary \( \partial f_2(G_\alpha) \) of domain \( f_2(G_\alpha) \) is a union \( \Gamma_2(\alpha) \cup \overline{\Gamma_2(\alpha)} \) of the contour
\[ \Gamma_2(\alpha) := \{f_2(\zeta_+(t))\}_{0 \leq t \leq \cos \alpha} \cup \{z : |z| \leq \sin^2 \alpha, \arg(z) = (\pi - 2\alpha)\} \]
and its conjugate \( \overline{\Gamma_2(\alpha)} \). Since \( \arg(\partial f_2(\zeta_+(t))) \leq (\pi - \alpha) \) for all \( 0 \leq t \leq \cos \alpha \), the contour
\[ \{f_2(\zeta_+(t))\}_{0 \leq t \leq \cos \alpha} \subseteq \{z : |\arg(z + 1)| > (\pi - \alpha)\}, \]
see (3.1). The same is obviously true for the image of the lower branch \( \zeta_-(t) \). If \( \alpha \leq \pi/4 \), one gets:
\[
\begin{align*}
\sup_{0 \leq t \leq \cos \alpha} \text{Im}(f_2(\zeta_+(t))) &= \text{Im}(f_2(\zeta_+(t^* = (2 \cos \alpha)^{-1}))) \\
&= \frac{1}{2} \tan \alpha < \sin \alpha \cos \alpha,
\end{align*}
\]

where \( t^* = (2 \cos \alpha)^{-1} \leq \cos \alpha \), and

\[
0 \geq \text{Re}(f_2(\zeta_+(t))) \geq -\sin^2 \alpha \cos^2 \alpha \geq -\sin \alpha.
\]

Therefore, \( \{f_2(\zeta_+(t))\}_{0 \leq t \leq \cos \alpha} \subseteq D_\alpha \). Since the same is also true for the image of the lower branch \( \zeta_-(t) \), we obtain \( f_2(G_\alpha) \subseteq D_\alpha \) and by consequence \( f_{n=2}(D_\alpha) = \{w = z \cdot z' : z \in D_\alpha, z \in f_{n=1}(D_\alpha)\} \subseteq D_\alpha \), for \( \alpha \leq \pi/4 \).

Now let \( n > 2 \) and suppose that \( f_n(D_\alpha) \subseteq D_\alpha \). Then the image of the \((n+1)\)-order mapping of domain \( D_\alpha \) is:

\[
f_{n+1}(D_\alpha) = \{w = z \cdot z'' : z \in D_\alpha, z'' \in f_n(D_\alpha)\},
\]

and since \( f_n(D_\alpha) \subseteq D_\alpha \), we obtain \( f_{n+1}(D_\alpha) \subseteq D_\alpha \) by the same reasoning as for \( n = 2 \).

\[\square\]

**Remark 3.1** Let \( \phi(t) := \arg(\zeta_+(t)) \). Then \( \cot(\alpha + \phi(t)) = (\cos \alpha - t)/\sin \alpha \) and

\[
\sup_{0 \leq t \leq \cos \alpha} \text{Im}(f_n(\zeta_+(t))) \leq (1 - 2t^*_n \cos \alpha + (t^*_n)^2)^{n/2}
\]

for \( \sin(n\phi(t^*_n)) = 1 \). In the limit \( n \to \infty \) this implies that \( \phi(t^*_n) = \pi/2n + o(n^{-1}) \), \( t^*_n = \pi/(2n \sin \alpha) + o(n^{-1}) \) and

\[
\lim_{n \to \infty} \sup_{0 \leq t \leq \cos \alpha} \text{Im}(f_n(\zeta_+(t))) \leq \exp(-\frac{1}{2}\pi \cot \alpha) < \frac{1}{2} \tan \alpha.
\]

By the same reasoning one gets the estimates similar to (3.3) and (3.4) for \( \zeta_-(t) \). Hence, \( |\text{Im}(f_n(\zeta_+(t)))| < \text{Im}(f_{n=1}(\zeta_+(t))) < \sin \alpha \cos \alpha \), cf. (3.2).

Notice that in spite of the arc-part of the contour \( \partial D_\alpha \) shrinks in the limit \( n \to \infty \) to zero, we obtain

\[
\lim_{n \to \infty} \sup_{0 \leq t \leq \cos \alpha} \text{Re}(f_n(\zeta_+(t))) = -\exp(-\pi \cot \alpha),
\]

for the left extreme point of the projection on the real axe \( (\sin(n\phi(t^*_n)) = 1) \) of the image \( f_n(D_\alpha) \). Since \( \exp(-\pi \cot \alpha) < \sin \alpha \), for \( \alpha \leq \pi/4 \), the arguments (3.4) and (3.5) bolster the conclusion of the Lemma 2.1.
Proof (Lemma 2.2): By (2.1) we have for $\lambda > 0$
\[
\|(\lambda I + A)^{-1}\| < \lambda^{-1},
\]
and since $A$ is $m$-sectorial, we also get that $(-\infty, 0) \subset \rho(A)$. Then the Hille-Yosida theory ensures the existence of the contraction semigroup $\{e^{-tA}\}_{t \geq 0}$, and the standards arguments (see e.g. [7, Ch.V], or [11, Ch.1.1]) yield the convergence of the Euler formula (2.3) in the strong topology. □

Proof (Theorem 2.1): Take $f(z) = z^2$ and the compact convex set $E' := f(D_\alpha) \subseteq D_\alpha$, see Lemma 2.1. Since the set $E := f^{-1}(E') = D_\alpha \cup (-D_\alpha)$ is convex, its convex kernel $K$ exists and $K = E$. Then by Proposition 2.2 we obtain that $\mathfrak{N}(f(C)) \subseteq E' \subseteq D_\alpha$, if the numerical range $\mathfrak{N}(C) \subseteq D_\alpha$. Then by the Kato numerical range mapping theorem (Proposition 2.2) we get:
\[
\mathfrak{N}(f(C_1) = F(t/2)^2) \subseteq E' \subseteq D_\alpha. \tag{3.7}
\]
Similarly, take the contraction $C_2 := F(t/4)^4$. Since (3.7) is valid for any $t \geq 0$, it is true for $t \mapsto t/2$. Then by definition of $K$ one has $\mathfrak{N}(F(t/4)^2) \subseteq D_\alpha \subseteq K$. Now again the Proposition 2.2 implies:
\[
\mathfrak{N}(f(C_2) = F(t/4)^4) \subseteq E' \subseteq D_\alpha. \tag{3.8}
\]
Therefore, we obtain $\mathfrak{N}(F_b(t/2^n)^{2^n}) \subseteq D_\alpha$, for any $n \in \mathbb{N}$. By Lemma 2.2 this yields
\[
\lim_{n \to \infty} (u, (I + tA/2^n)^{-2^n} u) = (u, e^{-tA}u) \in D_\alpha,
\]
for any unit vector $u \in \mathcal{H}$. Therefore, the numerical ranges of the contraction semigroup $\mathfrak{N}(e^{-tA}) \subseteq D_\alpha$ for all $t \geq 0$, if it is generated by $m$-sectorial operator with the semi-angle $\alpha \in [0, \pi/4]$ and with the vertex at $z = 0$. □

4 Corollaries and Applications

1. Notice that Definition 2.2 of quasi-sectorial contractions $C$ is quite restrictive comparing to the notion of general contractions, which demands only $\mathfrak{N}(C) \subseteq D_1$. For the latter case one has a well-known Chernoff lemma [5]:
\[
\|(C^n - e^{n(C-I)}u\| \leq n^{1/2}\|(C-I)u\|, \ u \in \mathcal{H}, \ n \in \mathbb{N}, \tag{4.1}
\]
which is not even a convergent bound. For quasi-sectorial contractions we can obtain a much stronger estimate [4]:

\[ \| C^n - e^{n(C-I)} \| \leq M n^{-1/3} , \quad n \in \mathbb{N} , \]  

convergent to zero in the uniform topology when \( n \to \infty \). Notice that the rate of convergence \( n^{-1/3} \) obtained in [4] with help of the Poisson representation and the Tchebychev inequality is not optimal. In [9], [2] and [1] this estimate was improved up to the optimal rate \( O(n^{-1}) \), which one can easily verify for a particular case of self-adjoint contractions (i.e. \( \alpha = 0 \)) with help of the spectral representation.

The inequality (4.2) and its further improvements are based on the following important result about the upper bound estimate for the case of quasi-sectorial contractions:

**Proposition 4.1** If \( C \) is a quasi-sectorial contraction on a Hilbert space \( \mathcal{H} \) with semi-angle \( 0 \leq \alpha < \pi/2 \), i.e. the numerical range \( \mathcal{N}(C) \) is a subset of the domain \( D_\alpha \), then

\[ \| C^n(I-C) \| \leq \frac{K}{n+1} , \quad n \in \mathbb{N} . \]  

For the proof see Lemma 3.1 of [4].

**Proposition 4.2** Let \( \{ \Phi(s) \}_{s \geq 0} \) be a family of uniformly quasi-sectorial contractions on a Hilbert space \( \mathcal{H} \), i.e. such that there exists \( 0 < \alpha < \pi/2 \) and \( \mathcal{N}(\Phi(s)) \subseteq D_\alpha \), for all \( s \geq 0 \). Let

\[ X(s) := (I - \Phi(s))/s , \]

and let \( X_0 \) be a closed operator with non-empty resolvent set, defined in a closed subspace \( \mathcal{H}_0 \subseteq \mathcal{H} \). Then the family \( \{ X(s) \}_{s > 0} \) converges, when \( s \to +0 \), in the uniform resolvent sense to the operator \( X_0 \) if and only if

\[ \lim_{n \to \infty} \left\| \Phi(t/n)^n - e^{-tX_0} P_0 \right\| = 0 , \quad \text{for } t > 0 . \]  

Here \( P_0 \) denotes the orthogonal projection onto the subspace \( \mathcal{H}_0 \).

3. We conclude by application of Theorem 2.1 and Proposition 4.1 to the Euler formula [4], [9], [2].
Proposition 4.3 If $A$ is an $m$-sectorial operator in a Hilbert space $\mathcal{H}$, with semi-angle $\alpha \in [0, \pi/4]$ and with vertex at $z = 0$, then

$$
\lim_{n \to \infty} \left\| (I + tA/n)^{-n} - e^{-tA} \right\| = 0, \quad t \in S_{\pi/2-\alpha}.
$$

Moreover, uniformly in $t \geq t_0 > 0$ one has the error estimate:

$$
\left\| (I + tA/n)^{-n} - e^{-tA} \right\| \leq O \left( n^{-1} \right), \quad n \in \mathbb{N}.
$$

Acknowledgements

I would like to thank Professor Mitsuru Uchiyama for a useful remark indicating a flaw in our arguments in Section 2 of [4], revision of this part of the paper [4] is done in the present manuscript. I also thankful to Vincent Cachia and Hagen Neidhardt for a pleasant collaboration.
